**Fitzroy Region**

**Shoalwater catchment water quality targets**

**Catchment profile**

Under the Reef 2050 Water Quality Improvement Plan, water quality targets have been set for each catchment that drains to the Great Barrier Reef. These targets (given over the page) consider land use and pollutant loads from each catchment.

The Shoalwater catchment covers 3601 km² (2% of the Fitzroy region). Rainfall averages 864 mm a year, which results in river discharges to the coast of about 996 GL each year.

The Shoalwater catchment lies on the coastal fringe of the Fitzroy region. The main waterway is Herbert Creek, which drains the western section of the catchment area and is dominated by grazing land use. The eastern section of the catchment is primarily reserved for conservation and for the Shoalwater Bay Military Training Area. The eastern coastal fringe of the catchment also contains Ramsar wetlands.

**Land uses in the Shoalwater catchment**

The main land uses are nature conservation (46%), grazing (41%), and water (13%).
The Shoalwater catchment has minimal anthropogenic pollutant loads. The aim is to maintain current water quality so that there are no increases in sediment or nutrient loads.

The 2025 targets aim to reduce the amounts of fine sediments, nutrients (nitrogen and phosphorus) and pesticides flowing to the reef. Each target for sediment and nutrients is expressed as: (a) the percentage load reduction required compared with the 2013 estimated load of each pollutant from the catchment; and (b) the load reductions required in tonnes. Progress made since 2013 will count towards these targets. Previously reported progress between 2009 and 2013 has already been accounted for when setting the targets. The pesticide target aims to ensure that concentrations of pesticides at the end of each catchment are low enough that 99% of aquatic species are protected. The targets are ecologically relevant for the Great Barrier Reef, and are necessary to ensure that broadscale land uses have no detrimental effect on the reef’s health and resilience.

A high percentage reduction target may not necessarily mean it is the highest priority. The priorities (ranked by colour) reflect the relative risk assessment priorities for water quality improvement, based on an independent report, the 2017 Scientific Consensus Statement. The priorities reflect scientific assessment of the likely risks of pollutants damaging coastal and marine ecosystems.
