

Jeannie catchment water quality targets

Catchment profile

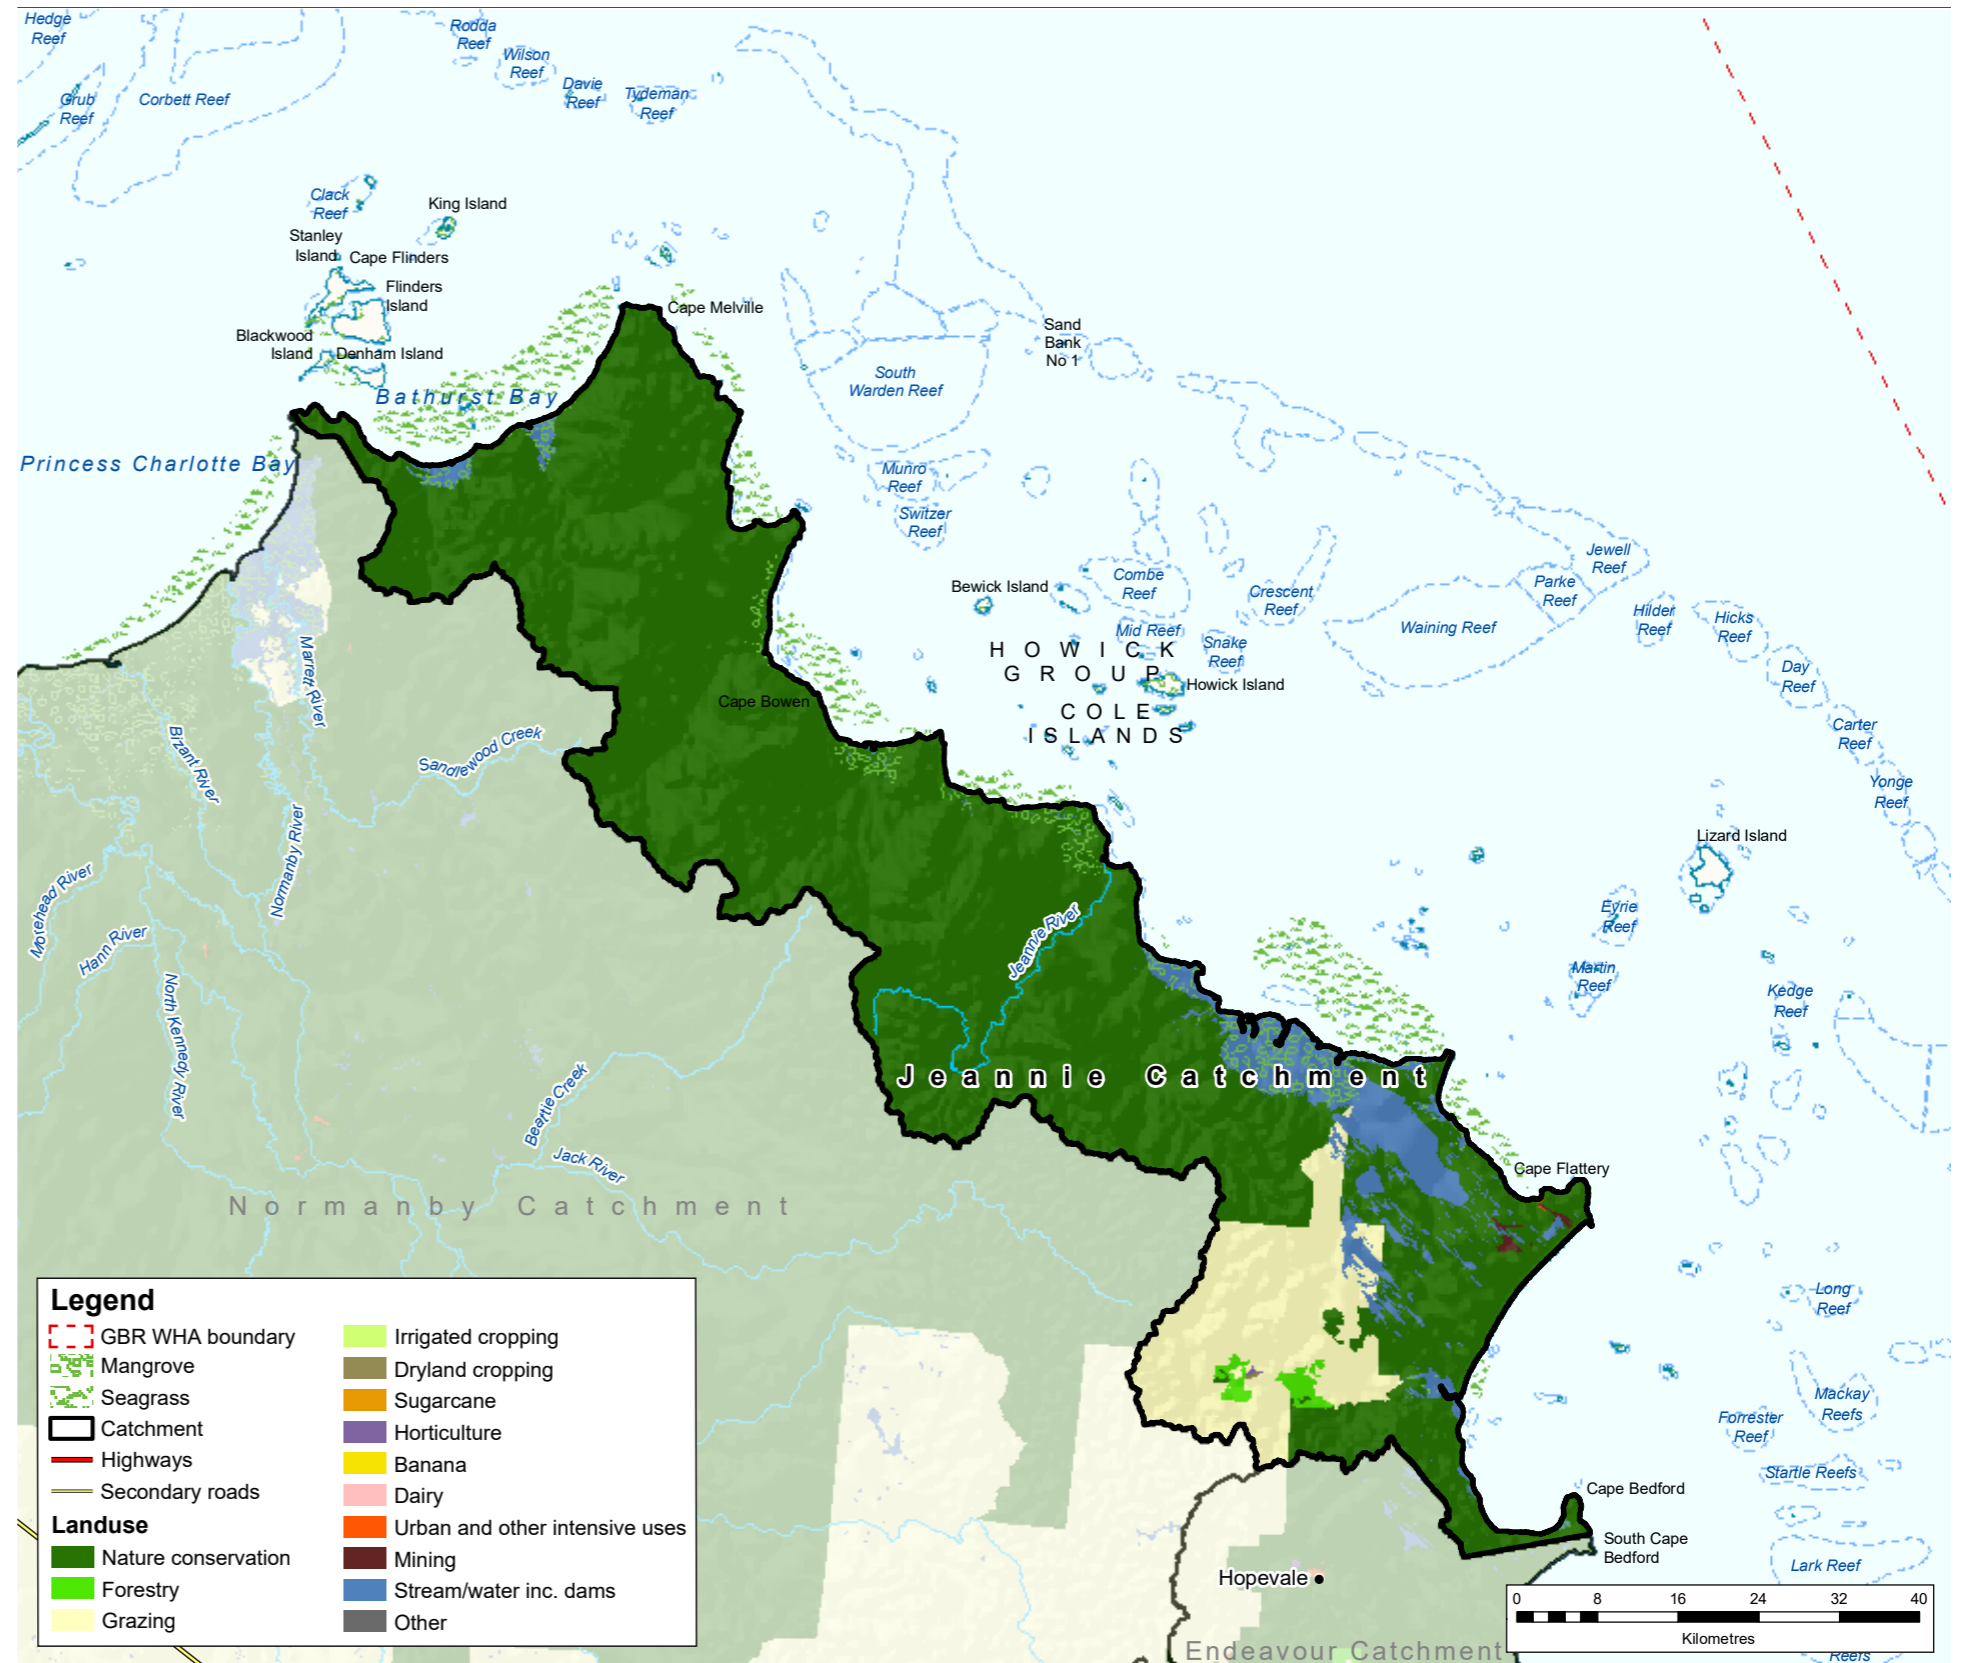

Under the Reef 2050 Water Quality Improvement Plan, water quality targets have been set for each catchment that drains to the Great Barrier Reef. These targets (given over the page) consider land use and pollutant loads from each catchment.

The Jeannie catchment covers 3638 km² (8% of the Cape York region). Rainfall averages 1345 mm a year, which results in river discharges to the coast of about 1432 GL each year.

The Jeannie catchment is in the southern section of the Cape York region. It occupies a narrow stretch along the east coast of the Cape York Peninsula adjacent to the Normanby catchment. A number of rivers flow east from the Great Dividing Range along the western boundary to the Coral Sea. These include (from north to south) the Muck, Howick, Jeannie, Starke and McIvor rivers. The majority of the Jeannie catchment remains undisturbed by human activities and is known for its unique ecosystems. The north and central parts of the catchment are reserved for natural and cultural conservation, with a very small proportion being for agricultural and urban land use in the south.

Land uses in the Jeannie catchment

The main land uses are nature conservation (81%), grazing (10%), and water (7%).

2025 water quality targets and priorities

End-of-catchment anthropogenic load reductions required from 2013 baseline

Dissolved inorganic nitrogen (DIN)	Fine sediment	Particulate phosphorus (PP)	Particulate nitrogen (PN)
maintain current load	6% 2 kilotonnes	6% 2 tonnes	6% 9 tonnes

The 2025 targets aim to reduce the amounts of fine sediments, nutrients (nitrogen and phosphorus) and pesticides flowing to the reef. Where there are minimal anthropogenic pollutant loads, the aim is to maintain current water quality so there are no increases in loads. Each target for sediment and nutrients is expressed as: (a) the percentage load reduction required compared with the 2013 estimated load of each pollutant from the catchment; and (b) the load reductions required in tonnes. Progress made since 2013 will count towards these targets. [Previously reported](#) progress between 2009 and 2013 has already been accounted for when setting the targets. The pesticide target aims to ensure that concentrations of pesticides at the end of each catchment are low enough that 99% of aquatic species are protected. The targets are ecologically relevant for the Great Barrier Reef, and are necessary to ensure that broadscale land uses have no detrimental effect on the reef's health and resilience.

A high percentage reduction target may not necessarily mean it is the highest priority. The priorities (ranked by colour) reflect the relative risk assessment priorities for water quality improvement, based on an independent report, the [2017 Scientific Consensus Statement](#). The priorities reflect scientific assessment of the likely risks of pollutants damaging coastal and marine ecosystems.

Pesticides

To protect at least **99%** of aquatic species at the end of catchment

Water quality relative priority

Modelled water quality pollutant loads

The Jeannie catchment has minimal anthropogenic dissolved inorganic nitrogen loads, and very small loads of fine sediment, mostly from grazing.

Fine sediment

Most anthropogenic fine sediment loads come from grazing, streambank erosion and forestry areas.

Types of sediment erosion

Most sediment erosion comes from hillslopes and gullies in the Jeannie catchment.
